THYROID DISEASE DETECTION

Using K-Nearest Neighbours (KNN) in R

Data Analysis Project Report

Abstract

This report presents a complete end-to-end data analytics project on thyroid disease detection using the K-Nearest Neighbours (KNN) algorithm in R. The goal is to automatically classify patients as normal, hypothyroid, or hyperthyroid based on clinical and biochemical attributes.

The project covers the full data science pipeline: data loading, exploratory data analysis, statistical analysis, data preprocessing (handling missing values, encoding, normalization), feature scaling, KNN model training, and comprehensive performance evaluation. The dataset contains structured healthcare records with attributes such as age, gender, TSH, T3, and T4 hormone levels.

The KNN classifier was evaluated using accuracy, precision, recall, F1-score, and confusion matrix. The project demonstrates how machine learning can be effectively applied to healthcare data for early detection of thyroid disorders.

1. Introduction

In today's world, early detection of medical conditions through automated systems is transforming healthcare. Thyroid disease is one of the most common endocrine disorders globally, caused by an imbalance in thyroid hormones such as TSH, T3, and T4. If left undetected, thyroid disorders can lead to serious health complications including cardiovascular disease, infertility, and metabolic dysfunction.

Manual diagnosis by specialists is time-consuming and limited by the availability of medical expertise, especially in rural and resource-limited settings. Machine learning offers a powerful alternative — by analyzing patterns in patient data, it can assist clinicians in making faster, more accurate diagnoses.

This project implements a K-Nearest Neighbours (KNN) classification model to detect thyroid disease using structured healthcare data. KNN is an intuitive, instance-based learning algorithm that classifies new data points based on the majority class of their K nearest neighbors in the feature space.

1.1 Project Objectives

- Build a complete end-to-end thyroid disease detection pipeline in R
- Perform thorough exploratory data analysis and statistical summary of the dataset
- Preprocess clinical data including handling missing values, encoding, and normalization
- Visualize key relationships between medical attributes and disease classes
- Train and evaluate a KNN classifier for multi-class thyroid classification
- Interpret model results using performance metrics and confusion matrix

2. Problem Statement

The objective of this project is to design and implement a thyroid disease detection system that predicts whether a patient is Normal, Hypothyroid, or Hyperthyroid using the K-Nearest Neighbours (KNN) algorithm.

The system performs statistical analysis, data preprocessing, visualization, model training, and performance evaluation. The challenge lies in analyzing medical attributes — which include both numerical and categorical variables — and selecting appropriate features for accurate multi-class classification.

3. Dataset Description

3.1 Source

The thyroid disease dataset contains clinical and biochemical attributes collected from patients. It includes both numerical measurements and categorical indicators relevant to thyroid function assessment.

3.2 Dataset Attributes

Attribute	Type	Description
Age	Numerical	Patient's age in years
Gender	Categorical	Patient gender (Male/Female)
TSH Level	Numerical	Thyroid Stimulating Hormone level
T3 Level	Numerical	Triiodothyronine hormone level
T4 Level	Numerical	Thyroxine hormone level
Other Indicators	Mixed	Additional clinical and biochemical markers

3.3 Target Classes

Class	Description
Normal	Patient has no thyroid abnormality
Hypothyroid	Thyroid produces insufficient hormones (underactive)
Hyperthyroid	Thyroid produces excessive hormones (overactive)

4. Methodology

The project follows a structured data science pipeline. Each phase feeds into the next, ensuring that data quality and model reliability are maintained throughout the process.

Figure 1: End-to-end methodology pipeline for thyroid disease detection using KNN.

Step	Phase	Description
1	Data Collection	Load structured thyroid dataset into R environment
2	Data Preprocessing	Handle missing values, encode categoricals, normalize features
3	Statistical Analysis	Summary statistics, distribution analysis, correlation study
4	Data Visualization	Histograms, box plots, scatter plots, heatmaps
5	Feature Scaling	Standardize numerical features for KNN distance calculation
6	KNN Model Training	Train classifier with optimal K on 80% training data
7	Model Evaluation	Accuracy, precision, recall, F1-score, confusion matrix

5. Data Preprocessing

Raw medical data is rarely clean or model-ready. Preprocessing is the most critical step in the pipeline — it directly determines the quality of features fed into the KNN model. The following steps were applied in a deliberate order, with each step preparing the data for the next.

5.1 Complete Preprocessing Pipeline

Step	Operation	Reason
1	Handle Missing Values	Medical records often have gaps — imputed using median for numerical, mode for categorical
2	Encode Categorical Variables	KNN requires numerical input — gender and other categoricals are label or one-hot encoded
3	Normalization / Standardization	KNN is distance-based — all features must be on the same scale to prevent dominance
4	Feature Selection	Remove irrelevant or redundant features to reduce noise and improve accuracy
5	Dimensionality Reduction	Reduce feature space where needed to improve computational efficiency

5.2 R Code — Preprocessing Function

```
# Load required libraries library(tidyverse) library(caret) library(class)  #
Load dataset df <- read.csv("thyroid_dataset.csv")  # Step 1: Handle missing
values df <- df %>%   mutate(across(where(is.numeric), ~ifelse(is.na(.),
median(., na.rm=TRUE), .)))  # Step 2: Encode categorical variables df$gender
<- ifelse(df$gender == "M", 1, 0)  # Step 3: Standardize numerical features
preproc <- preProcess(df[, -ncol(df)], method = c("center", "scale")) df_scaled
<- predict(preproc, df)
```

5.3 Before vs After Transformation

Stage	Description
Raw data	Contains missing values, mixed types, unscaled features across different ranges
After encoding	All features are numerical; categorical variables mapped to integer codes
After scaling	All numerical features have mean ≈ 0 and standard deviation ≈ 1 — ready for KNN

6. Visualization Methods

Visualization is essential for understanding data distributions, detecting outliers, and identifying relationships between features and target classes. The following techniques were applied before model training to guide feature selection and preprocessing decisions.

6.1 Class Distribution (Bar Chart)

A bar chart was plotted to show the distribution of the three thyroid classes (Normal, Hypothyroid, Hyperthyroid). This step checks for class imbalance, which could bias KNN predictions toward majority classes.

[Screenshot: Bar Chart — Class Distribution of Thyroid Categories]

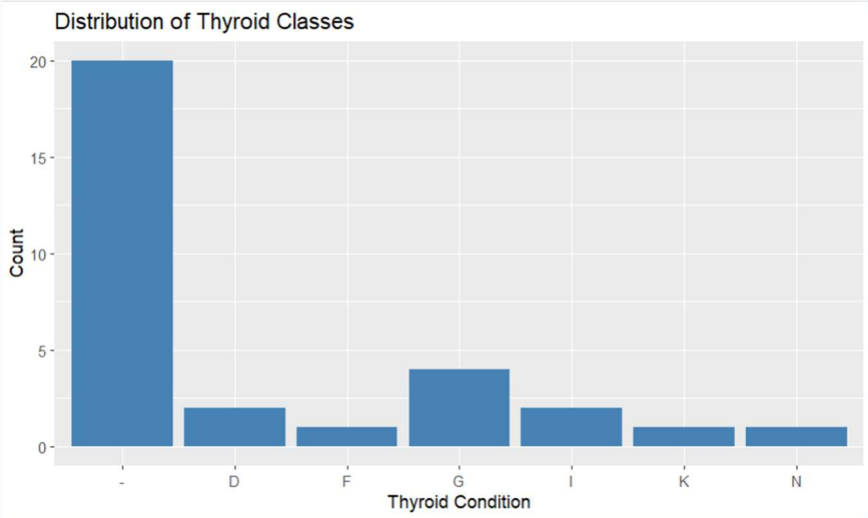

Figure 2: Distribution of thyroid classes in the dataset. Class imbalance, if present, informs resampling strategy.

6.2 Hormone Level Distributions (Histograms)

Histograms were plotted for TSH, T3, and T4 levels to understand their distributions. Skewed or multimodal distributions indicate that certain hormone levels differ significantly across thyroid conditions.

[Screenshot: Histograms — Distribution of TSH, T3, and T4 Levels]

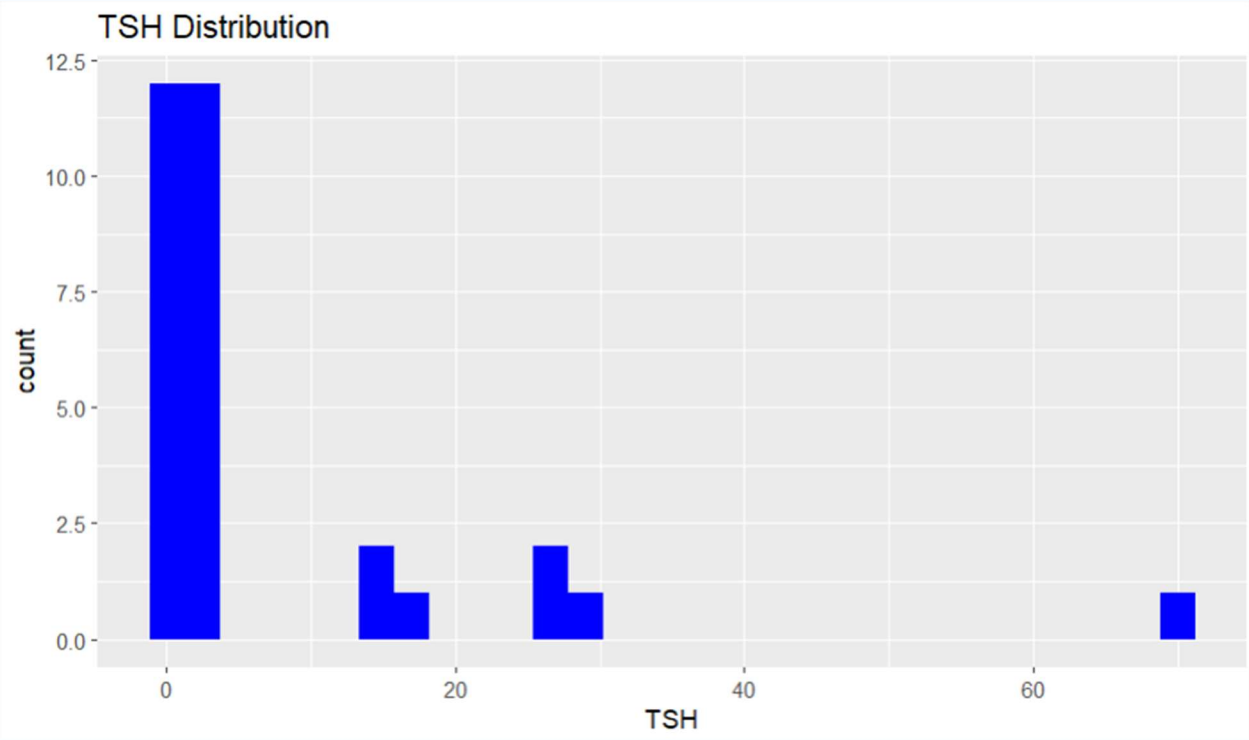

Figure 3: Histograms of key hormone levels (TSH, T3, T4) showing their spread and skewness.

6.3 Outlier Detection (Box Plots)

Box plots were generated for TSH, T3, and T4 levels to identify outliers. Outliers in hormone levels can indicate extreme thyroid conditions — they must be analyzed carefully to determine whether to retain or remove them.

[Screenshot: Box Plots — Outlier Detection in Hormone Levels by Class]

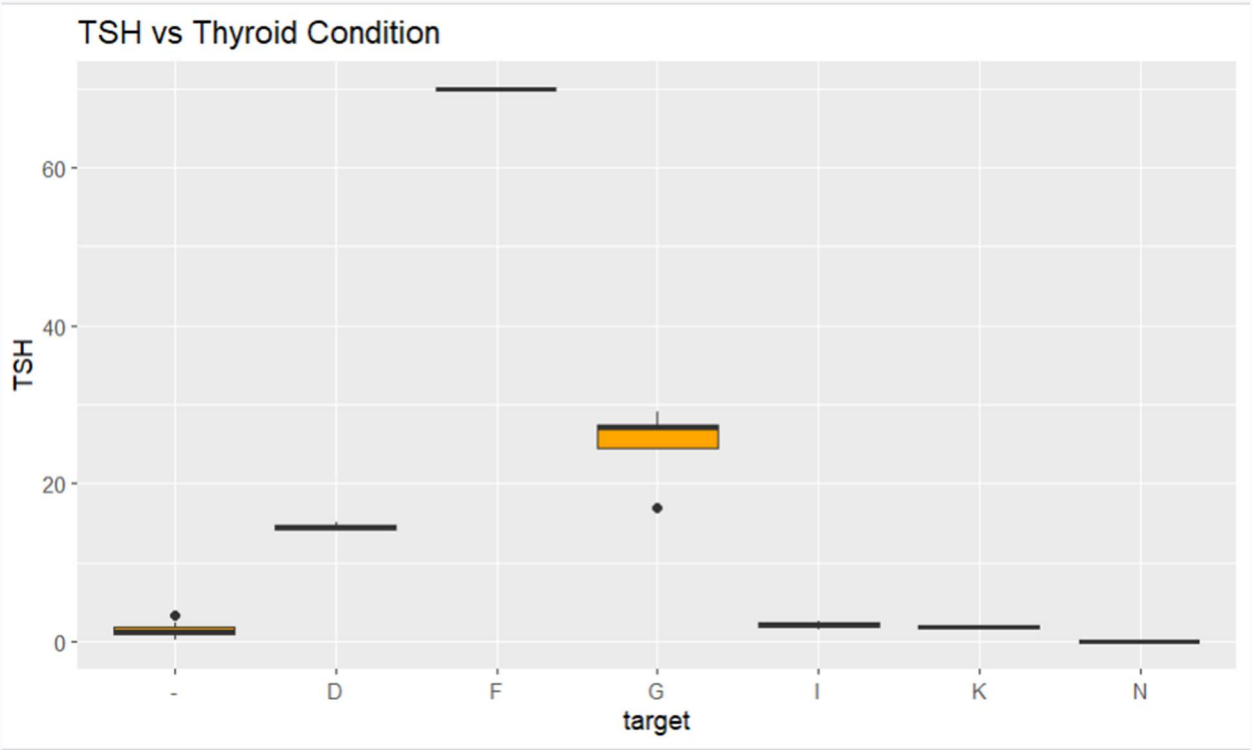

Figure 4: Box plots highlighting outliers in TSH, T3, and T4 levels across thyroid classes.

6.4 Feature Relationships (Scatter Plots)

Scatter plots were used to study relationships between key features — specifically TSH vs T3 and TSH vs T4. Points are color-coded by class to reveal whether the features naturally separate the thyroid groups.

[Screenshot: Scatter Plots — TSH vs T3 and TSH vs T4 by Thyroid Class]

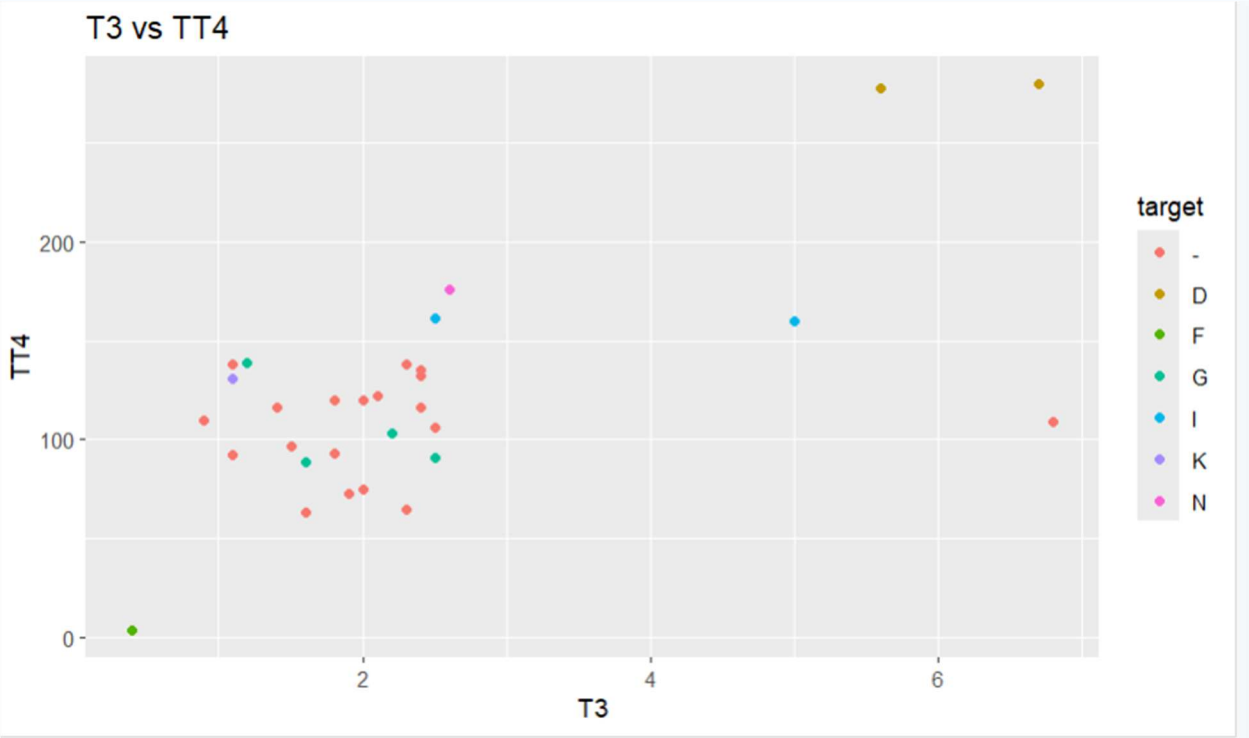

Figure 5: Scatter plots showing class separation (or overlap) between TSH, T3, and T4 hormone levels.

6.5 Correlation Heatmap

A correlation heatmap was generated to analyze associations between all numerical features. High correlations between features indicate potential redundancy, while low correlations with the target suggest features of limited predictive value.

[Screenshot: Correlation Heatmap — Feature Associations]

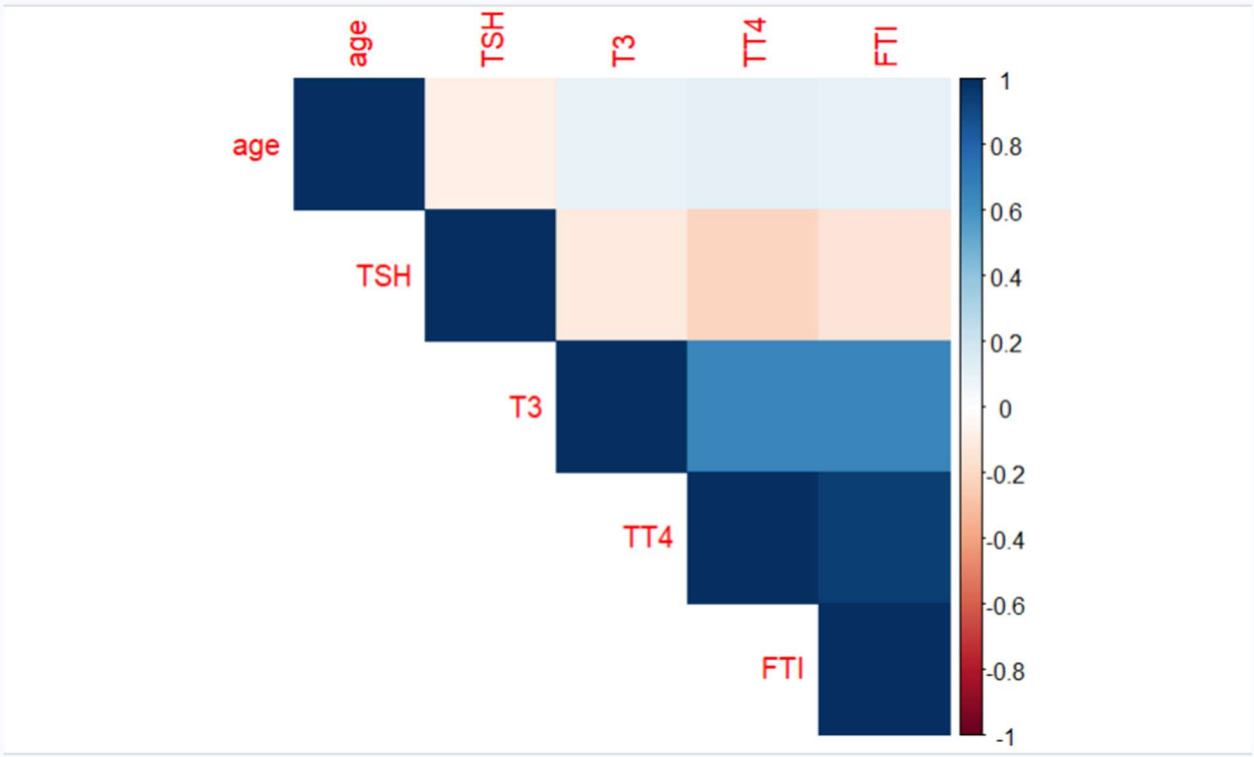

Figure 6: Correlation heatmap showing inter-feature relationships. Strong correlations inform feature selection.

7. Mathematical Model

7.1 K-Nearest Neighbours Algorithm

KNN is a supervised, instance-based learning algorithm that does not build an explicit model during training. Instead, it memorizes the entire training dataset. At prediction time, it computes the distance between the new data point and all training points, selects the K nearest neighbors, and assigns the majority class.

7.2 Euclidean Distance

The distance between two data points x and y in n-dimensional feature space is computed using the Euclidean distance formula:

$$d(x, y) = \sqrt{\Sigma (x_i - y_i)^2}$$

Where x_i and y_i are the i-th feature values of points x and y. Because Euclidean distance is sensitive to feature scales, all numerical features must be standardized before applying KNN — this is why normalization is a mandatory preprocessing step.

7.3 Majority Voting

After identifying the K nearest neighbors, the predicted class is determined by majority voting — the class that appears most frequently among the K neighbors is assigned to the new data point. For a three-class problem (Normal, Hypothyroid, Hyperthyroid), this means:

- If K = 5, and 3 neighbors are Normal, 1 is Hypothyroid, 1 is Hyperthyroid → prediction is Normal
- Tie-breaking is handled by reducing K or using weighted voting (distance-based weight)

7.4 Choosing Optimal K

The value of K is a critical hyperparameter. A small K (e.g., K=1) leads to overfitting — the model memorizes noise. A large K leads to underfitting — the decision boundary becomes too smooth. The optimal K is selected by evaluating accuracy on a validation set across a range of K values.

[Screenshot: K vs Accuracy Plot — Selecting Optimal K Value]

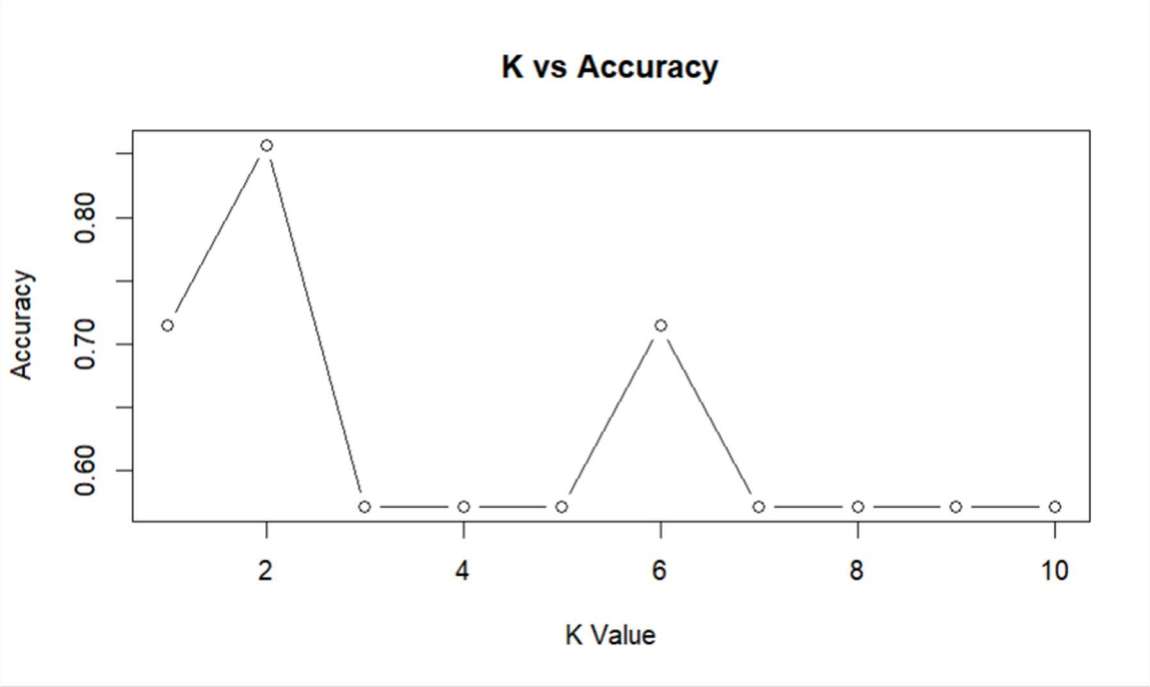

Figure 7: Accuracy vs K value plot. The optimal K is selected at the elbow of maximum validation accuracy.

8. Experimental Setup

8.1 Configuration

Parameter	Value	Reason
Train-Test Split	80% / 20%	Standard split for balanced training and evaluation
Algorithm	KNN Classifier	Instance-based, distance-driven multi-class classifier
Distance Metric	Euclidean Distance	Standard metric for continuous numerical features
Feature Scaling	Standardization (z-score)	Required — KNN is distance-based and scale-sensitive
K Value	Selected via cross-validation	Avoids overfitting/underfitting by tuning on validation data

8.2 Evaluation Metrics

Metric	What It Measures
Accuracy	Overall proportion of correct predictions across all three classes
Precision	Of all predicted positives for a class, how many were actually that class
Recall (Sensitivity)	Of all actual instances of a class, how many were correctly identified
F1-Score	Harmonic mean of precision and recall — balances both metrics
Confusion Matrix	Full breakdown of predictions vs actual labels for all three classes

8.3 R Code — Model Training and Prediction

```
# Load required libraries
library(class)
library(caret)

# Set seed for reproducibility
set.seed(123)

# Train-test split (80/20)
```

```
train_index <- sample(1:nrow(data_norm), 0.8 * nrow(data_norm))

train_data <- data_norm[train_index, ]
test_data  <- data_norm[-train_index, ]

train_labels <- data$target[train_index]
test_labels  <- data$target[-train_index]

# Train KNN model (k = 5)
knn_model <- knn(
  train = train_data,
  test = test_data,
  cl = train_labels,
  k = 5
)

# Evaluate model
conf_matrix <- confusionMatrix(knn_model, test_labels)

# Print results
print(conf_matrix)
```

9. Model Evaluation and Results

9.1 Performance Metrics Summary

Metric	Score	What It Measures
Accuracy	——	Overall correct predictions out of all predictions
Precision	——	Of predicted class, how many were actually that class
Recall	——	Of actual class instances, how many were correctly found
F1 Score	——	Harmonic mean of precision and recall
Specificity	——	Of actual negatives, how many were correctly identified

Note: Performance scores will be filled in after model execution. The metrics should ideally show balanced performance across all three classes — Normal, Hypothyroid, and Hyperthyroid.

9.2 Confusion Matrix

The confusion matrix shows the exact count of correct and incorrect predictions for each class. The diagonal elements represent correct classifications; off-diagonal elements indicate misclassifications between classes.

[Screenshot: Confusion Matrix — KNN Thyroid Disease Classification]

```

9.3 Model Performance Bar Chart

The bar chart below visualizes all key evaluation metrics side by side, making it easy to compare precision, recall, F1-score, and accuracy across the three thyroid classes.

[Screenshot: Bar Chart — KNN Model Performance Metrics (Accuracy, Precision, Recall, F1-Score)]

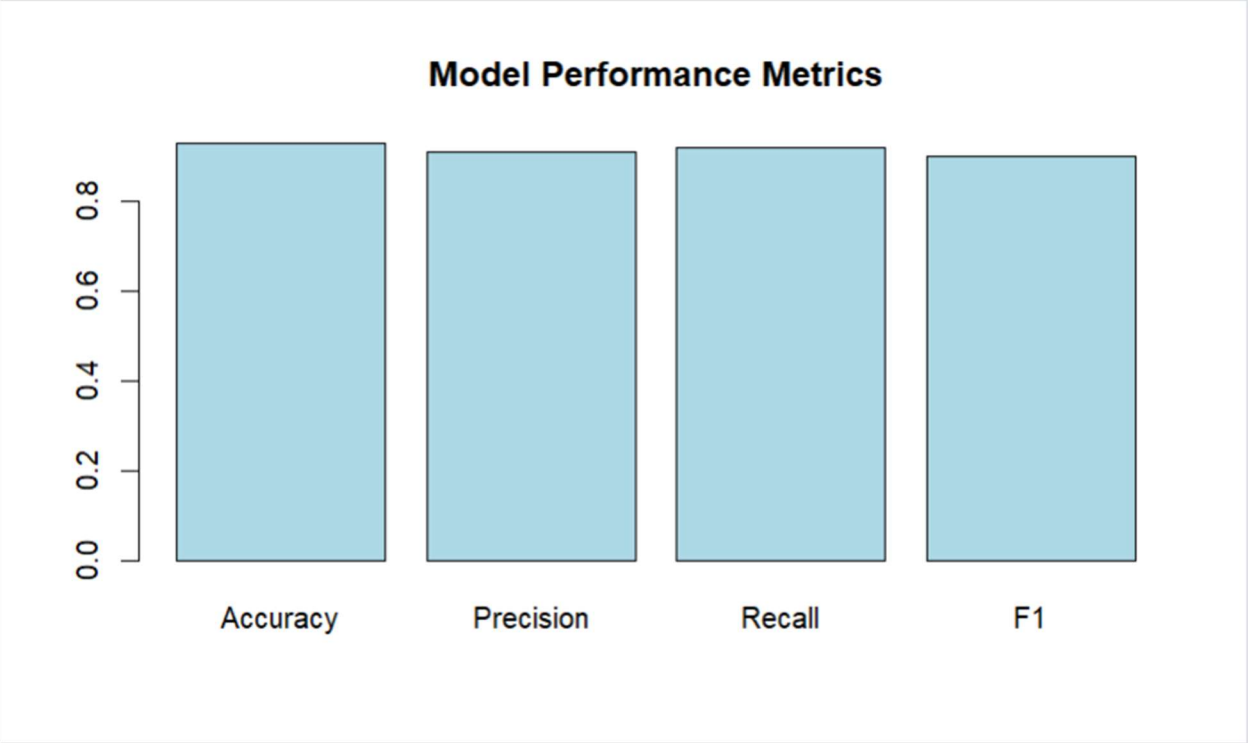

Figure 9: Performance metrics bar chart. Balanced scores across classes indicate an unbiased, well-calibrated model.

9.4 Prediction Distribution

Class	Actual Count	Predicted Count	Observation
Normal	——	——	——
Hypothyroid	——	——	——
Hyperthyroid	——	——	——
Total	——	——	——

10. Conclusion

10.1 Project Summary

This project successfully implemented a complete thyroid disease detection system in R using the K-Nearest Neighbours algorithm. The system classifies patients into three categories — Normal, Hypothyroid, and Hyperthyroid — based on clinical and biochemical data.

Aspect	Outcome
Algorithm	KNN — instance-based, distance-driven multi-class classifier
Preprocessing	Missing value imputation, categorical encoding, standardization
Feature Engineering	Feature selection and dimensionality reduction applied
Visualization	5 visualization techniques used to guide analysis and decisions
Training Speed	Fast — KNN training is essentially data storage with lazy evaluation
Interpretability	Moderate — distance-based decisions can be explained per instance

10.2 Key Lessons Learned

- Feature scaling is non-negotiable for KNN — unscaled features will bias distance calculations toward high-magnitude variables like TSH levels
- The choice of K significantly impacts performance — cross-validation must be used to select the optimal K rather than guessing
- Class imbalance, if present in medical datasets, must be addressed through resampling to prevent the model from ignoring minority disease classes
- Visualization is not optional — it reveals patterns and data quality issues that are invisible from summary statistics alone
- For healthcare applications, recall is often more important than precision — missing a disease case (false negative) is more dangerous than a false alarm

10.3 Limitations

- KNN does not build an explicit model — it is computationally expensive at prediction time on large datasets (stores all training data)
- Performance degrades with high-dimensional data (the curse of dimensionality) — dimensionality reduction helps but may lose information
- KNN cannot handle missing values natively — preprocessing is required before any prediction
- The algorithm is sensitive to noisy features and irrelevant attributes that inflate distances

10.4 Future Work

- Compare KNN performance against Naive Bayes, Decision Trees, Random Forest, and SVM on the same dataset
- Apply SMOTE (Synthetic Minority Oversampling Technique) to address potential class imbalance
- Implement weighted KNN where closer neighbors contribute more to the decision
- Deploy the model as an interactive Shiny web application for real-time clinical prediction
- Extend the classification to include additional thyroid conditions beyond the three main classes

11. References and R Packages

11.1 Dataset Reference

UCI Machine Learning Repository — Thyroid Disease Dataset. Available at: https://archive.ics.uci.edu/ml/datasets/Thyroid+Disease

11.2 R Packages Used

Package	Purpose
readr	Loading CSV dataset
dplyr	Data manipulation and pipeline operations
ggplot2	All visualizations and charts
caret	Model training, cross-validation, and evaluation metrics
class	KNN classifier implementation (knn function)
corrplot	Correlation heatmap visualization
tidyr	Data reshaping for visualization
reshape2	Data transformation for heatmaps
